But who could have known? In 2009, “SOA is dead: long live services” (Anne Thomas Manes, blog, http://mng.bz/dJn1) was groundbreaking news. Manes rightly stated in her blog that EAIs are not flexible enough—that as a monolith, they hinder development, and that the culprits are IT systems. They are the basis of the monolith and must be radically changed. But even if the word *SOA* is dead (see figure B.4), the call for service-oriented architecture is stronger than ever. Manes saw this clearly.

SOA was dying, but services are here to stay. When we talk about microservices today, we refer to the key features of a service-oriented architecture. These have not disappeared. All the features that came out of early middleware are still there; we need integration in general, interoperability, and governance.
