SOA architecture. If it was dead, we can say SOA was reborn in the microservices architecture.

These are the freedoms you gain when isolating services in different dimensions:

- Deployment
- Language
- Location
- Failure
- Time
- State

Now you can *deploy* your services in isolated containers. You can deploy as many replicas as you need, decoupling the various scaling requirements without disrupting other teams as you add new features or fix bugs. Deployment frequency is much greater and is decentralized, and releases can be customized to each team's schedule.

You have more leeway to use different languages and frameworks. In principle, each team could choose its own, but this needs to match the organization's needs to plan for the maintenance and evolution of these services in the longer term. In any case, the organization has a choice it didn't have before.

The idea of *location transparency or mobility* was present in the earlier SOA implementations. Today, using the container orchestration of your choice or another add-on like service mesh, you have an address that you can rely on, so any service can hide behind it. And the services that are accessible through that address can be
