When you create an actor, you must first specify the messages it can receive. It cannot receive just any type of message. You must define the actor's type, which in Akka terminology is called the actor's *protocol*.

2.2.1 The protocol of the actor

The Akka API specifies with `Behavior[Int]` that the behavior of the `Wallet` actor is such that it can receive messages of type `Int`. This is its protocol. In this example, the `Wallet` actor object has a protocol of type `Int` and is defined as follows:

```
import akka.actor.typed.Behavior

object Wallet {

  def apply(): Behavior[Int] = ...
}
```

The rest of the actor's code is not relevant at the moment. There could be many implementations, but the essential thing for the further development of the app is the definition of the messages the actor can receive.

2.2.2 Creating an application and instantiating the actor

Now that the protocol is set, you can create an application and add an actor using the `ActorSystem` you learned about in the previous chapter. An application is an executable program. You can
