create this application by defining an object that extends from `scala.App`:

```
object WalletApp extends App
```

This is a simple way to create a runnable class. At the end of the example, you learn how to run this class.

Next, let's focus on creating the actor in the signature of the `ActorSystem` constructor because the first parameter may not be clear. This is how you do it:

```
object WalletApp extends App {

  val guardian: ActorSystem[Int] = ActorSystem(Wallet(), "wallet")     ❶

}
```

❶ Instantiates an Akka application

In Scala, a generic type—equivalent to a Java generic—is identified by a letter in square brackets. The following snippet shows this generic type as `[T]` in the `ActorSystem` `apply` method, its constructor:

```
def apply[T](guardianBehavior: Behavior[T], name: String): ActorSystem[T]
```

NOTE Every `object` in Scala—like the `ActorSystem`—is created via the `apply` method, but it can also be created via the object's name alone. For example, the constructor `ActorSystem(myParameters)` refers to `ActorSystem.apply(myParameters)` under the covers.
