Another example is `Wallet()`, which references `Wallet.apply()`.

With this in mind, you can see how in `ActorSystem(Wallet(), "wallet")`, the first parameter refers to the wallet constructor, its `apply` method.

With this, you have an actor. Now let's send some messages to it.

## *2.2.3 Sending messages*

Two things are worth noting. First, the `Wallet` actor is instantiated as an `ActorSystem`, which is typed as [`Int`]. This signals what you already knew: that this actor can receive integers as messages only. Second, you may recall from chapter 1 that the `ActorSystem` is a reference to an actor, an `ActorRef`. This is the address you can use to send messages to the actor. To do this, you use the `tell` method, which is often represented with the bang operator (`!`). The following snippet means the numeral `1` is sent to the `myActorReference` address:

```
myActorReference ! 1
```

Combining all these ingredients, this snippet defines and instantiates the actor and sends two messages to it:

```
import akka.actor.typed.ActorSystem

object WalletApp extends App {

  val guardian: ActorSystem[Int] = ActorSystem(Wallet(), "wallet")  ❶
  guardian ! 1                                                      ❷
```
