```
  guardian ! 10                                                    ❷
}
```

❶ Creates the actor

❷ Sends messages to the actor

You send the actor first the integer 1 and then the integer 10. The type of the actor is `Int`, as explicitly set in `ActorSystem[Int]`. But you can also verify this is the case because the code compiles. In particular, the following lines compile:

```
guardian ! 1
guardian ! 10
```

If you send an `Int` to an actor that cannot receive `Int`, you get an error when compiling. The code will not compile, let alone run the application. This type checking—the fact that the application will not compile if you try to send something other than its message type—is one of the biggest improvements over previous versions of Akka. Another advantage is that if you change the protocol of an actor while refactoring, and the old protocol is still used elsewhere in the code, the compiler jumps to the rescue. The importance of this new feature can hardly be overestimated. Now let's look at how an actor receives messages.

2.2.4 Implementing the actor: Receiving messages

As you've seen, the complete type of this actor is `Behavior[Int]`. Let's see how to implement this behavior. To create a behavior, you use behavior factories. The
