`Behaviors.receive` factory is a function with two inputs, `context` and `message`: the context of the actor (`ActorContext`) and the message it receives (here, an `Int`). The factory creates a `Behavior` as output. This is the factory's signature:

```
object Wallet {

  def apply(): Behavior[Int] =
    Behaviors.receive { (context, message) =>     ❶
      ...
    }
}
```

❶ Signature of Behaviors.receive

In this factory, you can use the message and the context to, for example, log the received message. To do so, you can use `context` because one of the functions that comes with the context is logging. You can add something like the following:

```
object Wallet {

  def apply(): Behavior[Int] =
    Behaviors.receive { (context, message) =>
      context.log.info(s"received '$message' dollar(s)")     ❶
      ...
    }
}
```

❶ Logs each received message

Finally, you need to set the behavior for the next message. You can choose the same behavior using another behavior factory that you call with `Behaviors.same`. Together with the rest, you have the final implementation of the actor:
