2.2.7 The solution in Git

This wallet is implemented in the akka-topics repository. If you have cloned the akka-topics project, you will find a build.sbt file in its root directory. sbt uses this file to compile, run, and test the project. The project has several subprojects, one per chapter, so you can run them, test them, and play around while reading the book. Each subproject consists of the following:

- *Name*—Defined by a `val`.
- *File location*—The name of the subproject's folder relative to the build.sbt file.
- *Scala version*—Once this is set, Scala will be automatically downloaded from sbt.
- *Library dependencies*—The libraries used in the subproject. They will also be automatically downloaded from sbt.

All examples in this chapter are implemented in the chapter02 subproject defined in the file build.sbt shown in the following snippet:

```
val chapter02 = project
  .in(file("chapter02"))                                    ❶
  .settings(
    scalaVersion := "2.13.1",                               ❷
    libraryDependencies ++= Seq(
      "com.typesafe.akka" %% "akka-actor-typed" % "2.6.20",  ❸
      "ch.qos.logback" % "logback-classic" % "1.2.3"
      )
    )

...
```

❶ Folder where the project is located

❷ Scala version
