❶ 0 is the initial total, and 2 is its max.

❷ Sends messages

To run the app, type the following into the command line as before

```
$ project chapter02
$ run
```

but select `3`, `WalletStateApp`. Doing so generates the following output. The wallet logs the total up to the maximum value and then overloads:

```
INFO WalletState$ - increasing to 1
INFO WalletState$ - increasing to 2
INFO WalletState$ - I'm overloaded. Counting '3' while max is '2'. Stopping.
```

To store the total `amount` and the maximum value in the actor, you need to learn something new: how to create an actor while passing initial values to it. In the previous example, you created an actor without passing values during creation.

First, you need to add the two variables—the initial total and the maximum value—to the actor's constructor: that is, to the `def apply` method of the `Wallet` actor. Strictly speaking, they are not variables: in Scala they are called *values*—immutable variables. Adding these "variables" looks like this:

```
def apply(total: Int, max: Int): Behavior[Command]
```

Second, you must maintain the value of the two parameters from one call to the next (from one message to the next) in such a way that after the first increment, the `total` and `max` values are available when the next increment message arrives. To accomplish
