To run this app, select option 2 (`WalletOnOffApp`) in the sbt shell under the same subproject. The output is as follows:

```
INFO  [WalletOnOff$] - increasing to 1
INFO  [WalletOnOff$] - wallet is deactivated. Can't increase
INFO  [WalletOnOff$] - activating
INFO  [WalletOnOff$] - increasing to 2
```

You can provide this functionality with what you have already seen in this chapter. Creating more methods like `.apply` gives you multiple behaviors so you can refer from one to another.

To implement that the wallet has a default value of zero and its state is activated by default, you can do the following:

```
object WalletOnOff {

  ...

  def apply(): Behavior[Command] = activated(0)
     activated(0)

  ...
}
```

The `activated` behavior increments the total when an `Increment` message is processed and switches to the `deactivated` behavior when a `Deactivate` is processed. The wallet defines the `activated` and `deactivated` behaviors. Let's start with `activated`.

Listing 2.6 `activated` behavior in `WalletOnOff`

```
object WalletOnOff {

  ...
```
