```
internalServerError(new JSONObject()
.put("error", "internal server error").toString());
notFound(new JSONObject()
.put("error", "not found").toString());
exception(IllegalArgumentException.class, Main::badRequest);
exception(JSONException.class, Main::badRequest);
}
private static void badRequest(Exception ex,
Request request, Response response) {
response.status(400);
response.body(new JSONObject() #D
.put("error", ex.getMessage()).toString());
}
```

#A Enforce a correct Content-Type on all methods that receive input in the request body.
#B Return a standard 415 Unsupported Media Type response for invalid Content-Types.
#C Collect all your standard security headers into a filter that runs after everything else.
#D Use a proper JSON library for all outputs.

You should also alter your exceptions to not echo back malformed user input in any case. Although the security headers should prevent any bad effects, it’s best practice not to include user input in error responses just to be sure. It’s easy for a security header to be accidentally removed, so you should avoid the issue in the first place by returning a more generic error message:

```
if (!owner.matches("[a-zA-Z][a-zA-Z0-9]{0,29}")) {
throw new IllegalArgumentException("invalid username");
}
```
