```
  var rateLimiter = RateLimiter.create(2.0d);    #A

  before((request, response) -> {
    if (!rateLimiter.tryAcquire()) {    #B
      halt(429);
    }
  });
```

#A Create the shared rate limiter object and allow just 2 API requests per second.
#B If you can't acquire a permit from the rate limiter then you reject the request with an HTTP 429 Too Many Requests status.

Guava's rate limiter is quite basic, defining only a simple requests per second rate. It has some more features, such as being able to consume more permits for more expensive API operations. It lacks more advanced features such as being able to cope with occasional bursts of activity, but it's perfectly fine as a basic defensive measure that can be incorporated into an API in a few lines of code. You can try it out on the command line to see it in action:

```
$ for i in {1..5}
> do
>   curl -i -d "{\"owner\":\"test\",\"name\":\"space$i\"}"
[CA] -H 'Content-Type: application/json'
[CA] http://localhost:4567/spaces;
> done
HTTP/1.1 201 Created    #A
