Locate the pom.xml file in the project and open it with your favorite editor. Add the following Scrypt dependency to the dependencies section and then save the file:

```
        <dependency>
            <groupId>com.lambdaworks</groupId>
            <artifactId>scrypt</artifactId>
            <version>1.4.0</version>
        </dependency>
```

Before you can authenticate any users, you need some way to register them. For now, you'll just allow any user to register by making a POST request to the `/users` endpoint, specifying their username and chosen password. You'll add this endpoint in section 3.4.3, but first let's see how to store user passwords securely.

> **TIP** In a real project, you could confirm the user's identity during registration (by sending them an email or validating their credit card, for example), or you might use an existing user repository and not allow users to self-register.

You'll store users in a new dedicated database table, which you need to add to the database schema. Open the schema.sql file under src/main/resources in your text editor, and add the following table definition at the top of the file and save it:

```
CREATE TABLE users(
    user_id VARCHAR(30) PRIMARY KEY,
    pw_hash VARCHAR(255) NOT NULL
```
