```
);
```

You also need to grant the `natter_api_user` permissions to read and insert into this table, so add the following line to the end of the schema.sql file and save it again:

```
GRANT SELECT, INSERT ON users TO natter_api_user;
```

The table just contains the user id and their password hash. To store a new user, you calculate the hash of their password and store that in the `pw_hash` column. In this example, you'll use the Scrypt library to hash the password and then use Dalesbred to insert the hashed value into the database.

Listing 3.2 shows the Java code for a new UserController that implements secure password hashing using the Scrypt library you just added. Scrypt takes several parameters to tune the amount of time and memory that it will use. You do not need to understand these numbers, just know that larger numbers will use more CPU time and memory. You can use the recommended parameters as of 2019 (see https://blog.filippo.io/the-scrypt-parameters/ for a discussion of Scrypt parameters), which should take around 100ms on a single CPU and 32MiB of memory:

```
    String hash = SCryptUtil.scrypt(password, 32768, 8, 1);
```

This may seem an excessive amount of time and memory, but these parameters have been carefully chosen based on
