You have now enabled authentication for your API – every time a user makes a claim about their identity, they are required to authenticate to provide proof of that claim. You're not yet enforcing authentication on all API calls, so you can still read messages without being authenticated. You'll tackle that shortly, when you look at access control. The checks we have added so far are part of the application logic. Now let's try out how the API works. First, let's try creating a space without authenticating:

```
$ curl -i -d '{"name":"test space","owner":"demo"}'
[CA]-H 'Content-Type: application/json'
http://localhost:4567/spaces
HTTP/1.1 400 Bad Request
Date: Tue, 05 Feb 2019 11:56:19 GMT
Content-Type: application/json
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Cache-Control: private, max-age=0
Server:
Transfer-Encoding: chunked

{"error":"owner must match authenticated user"}
```

Good, that was prevented. Let's use curl now to register a demo user:

```
$ curl -i -d '{"username":"demo","password":"password"}'
[CA]-H 'Content-Type: application/json'
http://localhost:4567/users
HTTP/1.1 201 Created
Date: Tue, 05 Feb 2019 11:58:52 GMT
Location: /users/demo
Content-Type: application/json
```
