and private key. Leave the remaining arguments as `null`; these are only needed if you want to support client certificate authentication (which we will cover in chapter 11).

> **WARNING** The CA certificate and private key that `mkcert` generates can be used to generate certificates for any website that will be trusted by your browser. Do not share these files or send them to anybody. When you have finished development, consider running `mkcert -uninstall` to remove the CA from your system trust stores.

Listing 3.4 Enabling HTTPS

```
import static spark.Spark.secure;

public class Main {
  public static void main(String... args) throws Exception {
    secure("localhost.p12", "changeit", null, null);    #A
    ..
  }
}
```

#A Enable HTTPS support by calling the `secure()` static method.

Restart the server for the changes to take effect. If you started the server from the command line, then you can use Ctrl-C to interrupt the process and then simply run it again. If you started the server from your IDE, then there should be a button to restart the process.
