```
  String create(Request request, Token token);    #A
  Optional<Token> read(Request request, String tokenId);
#A

  class Token {
    public final Instant expiry;     #B
    public final String username;    #B
    public final Map<String, String> attributes;    #B

    public Token(Instant expiry, String username) {
      this.expiry = expiry;
      this.username = username;
      this.attributes = new ConcurrentHashMap<>();    #C
    }
  }
}
```

#A A token can be created and then later looked up by token ID.
#B A token has an expiry time, an associated username, and a set of attributes.
#C Use a concurrent map if the token will be accessed from multiple threads.

In section 4.4, you'll implement a token store based on session cookies, using Spark's built-in cookie support. Then in chapters 5 and 6 you'll see more advanced implementations using databases and encrypted client-side tokens for high scalability.

4.2.2 Implementing token-based login
