```
import static java.time.Instant.now;

public class TokenController {

    private final TokenStore tokenStore;    #A

    public TokenController(TokenStore tokenStore) {    #A
        this.tokenStore = tokenStore;    #A
    }

    public JSONObject login(Request request, Response
response) {
        String subject = request.attribute("subject");    #B
        var expiry = now().plus(10, ChronoUnit.MINUTES);
#B

        var token = new TokenStore.Token(expiry, subject);
#C
        var tokenId = tokenStore.create(request, token);
#C

        response.status(201);
        return new JSONObject()    #C
                .put("token", tokenId);    #C
    }
}
```

#A Inject the token store as a constructor argument.
#B Extract the subject username from the request and pick a suitable expiry time.
#C Create the token in the store and return the token ID in the response.

You can now wire up the `TokenController` as a new endpoint that clients can call to login and get a session
