

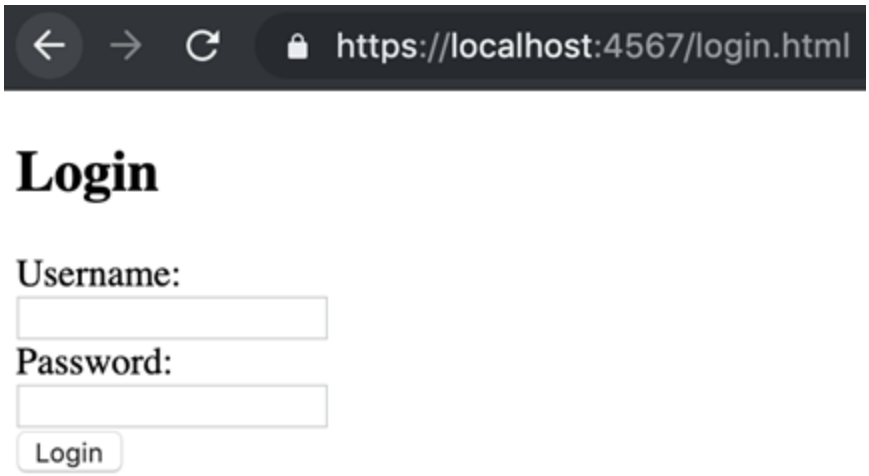

Figure 4.13 The login UI features a simple username and password form. Once successfully submitted, the form will redirect back to the main natter.html UI page that you built earlier.

While it is possible to intercept the 401 response from the API in JavaScript, it is not possible to stop the browser popping up the ugly default login box when it receives a WWW-Authenticate header prompting it for Basic authentication credentials. To get around this, you can simply remove that header from the response when the user is not authenticated. Open the UserController.java file in your editor and update the `requireAuthentication` method to omit this header on the response. The new implementation is shown in listing 4.13. Save the file when you are happy with the change.

Listing 4.13 The updated authentication check

```
public void requireAuthentication(Request request, Response
response) {
    if (request.attribute("subject") == null) {
```
