- You also cannot read the anti-CSRF token, so cannot make requests from the new site even if the user is already logged in.

Moving to an alternative token storage mechanism solves only the second issue, but if you want to allow cross-origin requests to your API from browser clients you'll need to solve the others. The solution is the CORS standard, introduced in 2013 to allow the SOP to be relaxed for some cross-origin requests.

There are several ways to simulate cross-origin requests on your local development environment, but the simplest is to just run a second copy of the Natter API and UI on a different port[1]. (Remember that *an origin is the combination of protocol, host name, and port*, so a change to any of these will cause the browser to treat it as a separate origin). To allow this, open Main.java in your editor and add the following line to the top of the method before you create any routes to allow Spark to use a different port:

```
    port(args.length > 0 ? Integer.parseInt(args[0])
                         : SPARK_DEFAULT_PORT);
```

You can now start a second copy of the Natter UI by running the following command:

```
mvn clean compile exec:java -Dexec.args=9999
```
