```
        }    #C
        return token;    #C
    }

    @Override
    public void revoke(Request request, String tokenId) {
        database.update("DELETE FROM tokens WHERE token_id =
?",    #D
                tokenId);     #D
    }
}
```

#A Use a SecureRandom to generate unguessable token IDs
#B Serialize the token attributes as JSON
#C Use a helper method to reconstruct the token from the JSON
#D Revoke a token on logout by deleting it from the database.

All that remains is to plug in the `DatabaseTokenStore` in place of the `CookieTokenStore`. Open Main.java in your editor and locate the lines that create the `CookieTokenStore`. Replace them with code to create the `DatabaseTokenStore`, passing in the Dalesbred Database object:

```
    TokenStore tokenStore = new DatabaseTokenStore(database);
    var tokenController = new TokenController(tokenStore);
```

Save the file and restart the API to see the new token storage format at work. First create a test user, as always:

```
curl -H 'Content-Type: application/json' \
  -d '{"username":"test","password":"password"}' \
  https://localhost:4567/users
```
