you could do this in production. Some frameworks include a scheduler for these kinds of tasks, or you could expose the method as a REST endpoint and call it periodically from an external job. If you do this, remember to apply rate-limiting to that endpoint or require authentication (or a special permission) before it can be called, as in the following example:

```
before("/expired_tokens",
userController::requireAuthentication);
delete("/expired_tokens", (request, response) -> {
    databaseTokenStore.deleteExpiredTokens();
    return new JSONObject();
});
```

For now, you can use a simple Java scheduled executor service to periodically call the method. Open DatabaseTokenStore.java again and add the following lines to the constructor:

```
 Executors.newSingleThreadScheduledExecutor()
         .scheduleAtFixedRate(this::deleteExpiredTokens,
                 10, 10, TimeUnit.MINUTES);
```

This will cause the method to be executed every 10 minutes, after an initial 10-minute delay. If a cleanup job takes more than 10 minutes to run then the next run will be scheduled immediately after it completes.
