for your APIs and can be significantly easier to use securely than alternatives.

> **TIP** Other cryptographic libraries designed to be hard to misuse include Google's Tink (https://github.com/google/tink) and Themis from Cossack Labs (https://github.com/cossacklabs/themis). The Sodium library (https://libsodium.org) is a widely used clone of NaCl in C that provides many additional extensions and a simplified API with bindings for Java and other languages.

In this section you'll use a pure Java implementation of NaCl called Salty Coffee (https://github.com/NeilMadden/salty-coffee), which provides a very simple and Java-friendly API with acceptable performance.[2] To add the library to the Natter API project, open the pom.xml file in the root folder of the Natter API project and add the following lines to the dependencies section:

```
<dependency>
  <groupId>software.pando.crypto</groupId>
  <artifactId>salty-coffee</artifactId>
  <version>1.0.2</version>
</dependency>
```

Listing 6.5 shows an `EncryptedTokenStore` implemented using the Salty Coffee library's `SecretBox` class, which provides authenticated encryption. Like the `HmacTokenStore`, you can delegate creating the token to another store, allowing this to be wrapped around the `JsonTokenStore` or another format. Encryption is then performed with the `SecretBox.encrypt()`
