`EncryptedTokenStore`, wrapping a `JsonTokenStore`, instead of the previous JWT-based implementation:

```
    var naclKey = SecretBox.key(encKey.getEncoded());    #A
    var tokenStore = new EncryptedTokenStore(    #B
                new JsonTokenStore(), naclKey);    #B
    var tokenController = new TokenController(tokenStore);
```

#A Convert the key to the correct format
#B Construct the EncryptedTokenStore wrapping a JsonTokenStore

You can now restart the API and login again to get a new encrypted token.

## 6.3.3 Encrypted JWTs

NaCl's `SecretBox` is hard to beat for simplicity and security, but there is no standard for how encrypted tokens are formatted into strings and different libraries may use different formats or leave this up to the application. This is not a problem when tokens are only consumed by the same API that generated them but can become an issue if tokens are shared between many APIs, developed by separate teams in different programming languages. A standard format such as JOSE becomes more compelling in these cases. JOSE supports several authenticated encryption algorithms in the JSON Web Encryption (JWE) standard.

An encrypted JWT using the JWE Compact Serialization looks superficially like the HMAC JWTs from section 6.2, but there are more components reflecting the more complex structure
