#C When passed a ConfidentialTokenStore return a SecureTokenStore
#D When passed any other TokenStore return

You can now update the `TokenController` class to require a `SecureTokenStore` to be passed to it. Open TokenController.java in your editor and update the constructor to take a `SecureTokenStore`:

```
    public TokenController(SecureTokenStore tokenStore) {
        this.tokenStore = tokenStore;
    }
```

This change makes it much harder for a developer to accidentally pass in an implementation that doesn't meet your security goals, because the code will fail to type-check. For example, if you try to pass in a plain `JsonTokenStore` then the code will fail to compile with a type error. These marker interfaces also provide valuable documentation of the expected security properties of each implementation, and a guide for code reviewers and security audits to check that they achieve them.

6.5 Handling token revocation

Stateless self-contained tokens such as JWTs are great for moving state out of the database. On the face of it, this increases the ability to scale up the API without needing additional database hardware or more complex deployment topologies. It's also much easier to set up a new API with just an encryption key rather than needing to deploy a new
