```
        }

        return jwt.serialize();
    }
```

#A Inject a DatabaseTokenStore into the JwtTokenStore to use for the whitelist.
#B Save a copy of the token in the database but remove all the attributes to save space.
#C Save the database token ID in the JWT as the JWT ID claim.

To revoke a JWT you then simply delete it from the database token store, as shown in listing 6.16. Parse and decrypt the JWT as before, which will validate the authentication tag, and then extract the JWT ID and revoke it from the database. This will remove the corresponding record from the database. While you still have the JwtTokenStore.java open in your editor, add the implementation of the revoke method from the listing.

Listing 6.16 Revoking a JWT in the database whitelist

```
@Override
public void revoke(Request request, String tokenId) {
    try {
        var jwt = EncryptedJWT.parse(tokenId);    #A
        var decryptor = new DirectDecrypter(encKey);    #A
        jwt.decrypt(decryptor);     #A
        var claims = jwt.getJWTClaimsSet();    #A

        tokenWhitelist.revoke(request, claims.getJWTID());
#B
    } catch (ParseException | JOSEException e) {
```
