should check the documentation for your AS to determine how the RS must authenticate.

> **TIP** To avoid historical issues with ambiguous character sets, OAuth requires that HTTP Basic authentication credentials are first URL-encoded (as UTF-8) before being Base64-encoded.

Listing 7.5 shows the constructor and imports for a new token store that will use OAuth2 token introspection to validate an access token. You'll implement the remaining methods in the rest of this section. The `create` and `revoke` methods throw an exception, effectively disabling the login and logout endpoints at the API, forcing clients to obtain access tokens from the AS. The new store takes the URI of the token introspection endpoint, along with the credentials to use to authenticate. The credentials are encoded into an HTTP Basic authentication header ready to be used. Navigate to `src/main/java/com/manning/apisecurityinaction/token` and create a new file named `OAuth2TokenStore.java`. Type in the contents of listing 7.5 in your editor and save the new file.

**Listing 7.5 The OAuth2 token store**
