```
    if (hash.isPresent() && SCryptUtil.check(password,
hash.get())) {
        request.attribute("subject", username);

        var groups = database.findAll(String.class,     #A
            "SELECT DISTINCT group_id FROM group_members "
+    #A
                    "WHERE user_id = ?", username);    #A
        request.attribute("groups", groups);    #B
    }
```

#A Lookup all groups that the user belongs to.
#B Set the user's groups as a new attribute on the request.

You can then either change the `permissions` table to allow either a user or group ID to be used (dropping the foreign key constraint to the users table)

```
CREATE TABLE permissions(
    space_id INT NOT NULL REFERENCES spaces(space_id),
    user_or_group_id VARCHAR(30) NOT NULL,    #A
    perms VARCHAR(3) NOT NULL);
```

#A Allow either a user or group ID.

or you can create two separate permission tables and define a view that performs a union of the two:

```
CREATE TABLE user_permissions(…);
CREATE TABLE group_permissions(…);
CREATE VIEW permissions(space_id, user_or_group_id, perms) AS
    SELECT space_id, user_id, perms FROM user_permissions
    UNION ALL
```
