```
    SELECT space_id, group_id, perms FROM group permissions;
```

To determine if a user has appropriate permissions you would then query first for individual user permissions and then for permissions associated with any groups the user is a member of. This can be accomplished in a single query, as shown in listing 8.2, which adjusts the `requirePermission` method in `UserController` to take groups into account by building a dynamic SQL query that checks the permissions table for both the username from the subject attribute of the request and any groups the user is a member of. Dalesbred has support for safely constructing dynamic queries in its `QueryBuilder` class, so you can use that here for simplicity.

> **TIP** When building dynamic SQL queries, be sure to use only placeholders and never include user input directly in the query being built to avoid SQL injection attacks, which are discussed in chapter 2. Some databases support *temporary tables*, which allow you to insert dynamic values into the temporary table and then perform a SQL `JOIN` against the temporary table in your query. Each transaction sees its own copy of the temporary table, avoiding the need to generate dynamic queries.

Listing 8.2 Taking groups into account when looking up permissions

```
public Filter requirePermission(String method, String
permission) {
    return (request, response) -> {
        if (!method.equals(request.requestMethod())) {
```
