- The API doesn’t need to directly communicate with the third-party service.
- No details about the query being answered by the third-party service are disclosed to the client. This can be important if the query contains personal information about a user.
- The discharge macaroon proves that the caveat is satisfied without revealing any details to the client or the API.
- As the discharge macaroon is itself a macaroon, the third-party service can attach additional caveats to it that the client must satisfy before it is granted access, including further third-party caveats.

To add a third-party caveat to a macaroon, you use the `add_third_party_caveat` method on the `MacaroonsBuilder`:

```
macaroon = MacaroonsBuilder.modify(macaroon) #A
.add_third_party_caveat("https://auth.example.com", #B
secret, caveatId) #B
.getMacaroon();
```

#A Modify an existing macaroon to add a caveat.
#B Add the third-party caveat.

A third-party caveat takes three arguments rather than the single string used for first-party caveats:

- A location hint telling the client where to locate the third-party service.
