monoliths, where all the components of an application are bundled into a single deployed unit. Microservices communicate with each other using APIs over a protocol such as HTTP.

Some microservices may also need to call APIs provided by external services, such as a third-party payment processor. In this chapter you'll learn how to securely deploy microservice APIs as Docker containers on Kubernetes, including how to harden containers and the cluster network to reduce the risk of compromise, and how to run TLS at scale using Linkerd (https://linkerd.io) to secure microservice API communications.
