9092 so that the server can be accessed from outside the container and configure it to use a non-root user and group to run the server. Finally, define the command to run to start the server using the `ENTRYPOINT` command.

> TIP Using a minimal base image such as the Alpine distribution or Google's distroless images reduces the *attack surface* of potentially vulnerable software and limits further attacks that can be carried out if the container is ever compromised. In this case, an attacker would be quite happy to find curl on a compromised container, but this is missing from the distroless image as is almost anything else they could use to further an attack. Using a minimal image also reduces the frequency with which you'll need to apply security updates to patch known vulnerabilities in the distribution as the vulnerable components are not present.

Listing 10.1 The H2 database Dockerfile

```
FROM curlimages/curl:7.66.0 AS build-env

ENV RELEASE h2-2018-03-18.zip    #A
ENV SHA256 \

a45e7824b4f54f5d9d65fb89f22e1e75ecadb15ea4dcf8c5d432b80af59ea
759    #A

WORKDIR /tmp

RUN echo "$SHA256  $RELEASE" > $RELEASE.sha256 && \
    curl -sSL https://www.h2database.com/$RELEASE -o $RELEASE
&& \    #B
```
