```
var jdbcUrl =     #A
    "jdbc:h2:tcp://natter-database-
service:9092/mem:natter";    #A
var datasource = JdbcConnectionPool.create(
    jdbcUrl, "natter", "password");    #B
createTables(datasource.getConnection());
datasource = JdbcConnectionPool.create(
    jdbcUrl, "natter_api_user", "password");    #B
var database = Database.forDataSource(datasource);
```

#A Use the DNS name of the remote database service
#B Use the same JDBC URL when creating the schema and when switching to the Natter API user

To build the Docker image for the Natter API with Jib you can then simply run the following Maven command in the same shell in the root folder of the natter-api project:

```
mvn clean compile jib:dockerBuild
```

This should be quite quick because it can reuse the base image from when you built the H2 image. You can then test that the image runs by running the following command:

```
docker run apisecurityinaction/natter-api
```

This command will start the API server in the Docker container. Once you have verified that the container starts up correctly, then type Ctrl-C to shut down the process again. You can now create a deployment to run the API in the cluster. Listing 10.7 shows the deployment
