#B Start a database transaction.
#C Generate a fresh ID for the social space.
#D Return a 201 Created status code with the URI of the space in the Location header.

2.3 Wiring up the REST endpoints

Now that you've created the controller, you need to wire it up so that it will be called when a user makes a HTTP request to create a space. To do this, you'll need to create a new Spark *route* that describes how to match incoming HTTP requests to methods in our controller objects.

> **DEFINITION** A ***route*** defines how to convert a HTTP request into a method call for one of your controller objects. For example, a HTTP POST method to the `/spaces` URI may result in a `createSpace` method being called on the `SpaceController` object.

In listing 2.5, you'll use static imports to access the Spark API. This is not strictly necessary, but it's recommended by the Spark developers as it can make the code more readable. Then you need to create an instance of your `SpaceController` object that you created in the last section, passing in the Dalesbred `Database` object so that it can access the database. You can then configure Spark routes to call methods on the controller object in response to HTTP requests. For example, the following line of code arranges for the createSpace method to be called when a HTTP POST request is received for the /spaces URI:
