```
            throw new IllegalArgumentException(    #B
                    "URL refers to local/private
address");    #B
        }    #B
        var res =
Jsoup.connect(url).followRedirects(false)    #C
                .timeout(3000).method(GET).execute();
        if (res.statusCode() / 100 == 3) {    #D
            url = res.header("Location");    #D
        } else {
            doc = res.parse();    #E
        }
    }
    if (doc == null) throw new IOException("too many
redirects");
    return doc;
}
```

#A Loop until the URL resolves to a document. Set a limit on the number of redirects.
#B If any URL resolves to a private-use IP address then reject the request.
#C Disable automatic redirect handling in Jsoup.
#D If the site returns a redirect status code (3xx in HTTP) then update the URL.
#E Otherwise parse the returned document.

Pop quiz

Q.4 Which one of the following is the most secure way to validate URLs to prevent SSRF attacks?

a. Only performing GET requests
b. Only performing HEAD requests
c. Blacklisting private-use IP addresses
d. Limiting the number of requests per second
e. Strictly match the URL against a whitelist of known safe values
