On other platforms it can be downloaded and installed from https://github.com/linkerd/linkerd2/releases/. Once you've installed the CLI, you can run pre-installation checks to ensure that your Kubernetes cluster is suitable for running the service mesh by running

```
linkerd check --pre
```

If you've followed the instructions for installing minikube in this chapter then this will all succeed. You can then install the control plane components by running the following command:

```
linkerd install | kubectl apply -f -
```

Finally, run `linkerd check` again (without the --pre argument) to check the progress of the installation and see when all the components are up and running. This may take a few minutes as it downloads the container images.

To enable the service mesh for the Natter namespace, edit the namespace YAML file to add the linkerd annotation, as shown in listing 10.18. This single annotation will ensure that all pods in the namespace have Linkerd sidecar proxies injected the next time they are restarted. Run the following command to update the namespace definition:

```
kubectl apply -f kubernetes/natter-namespace.yaml
```
