```
"$service_name.$namespace.svc.cluster.local:$service_port"
#C
spec:
  tls:    #D
    - hosts:    #D
        - api.natter.local    #D
      secretName: natter-tls    #D
  rules:    #E
    - host: api.natter.local    #E
      http:    #E
        paths:    #E
          - backend:    #E
              serviceName: natter-api-service    #E
              servicePort: 4567    #E
```

#A Define the Ingress resource
#B Give the ingress rules a name in the natter-api namespace
#C Rewrite the Host header using the upstream-vhost annotation
#D Enable TLS by providing a certificate and key
#E Define a route to direct all HTTP requests to the natter-api-service

To allow the ingress controller to terminate TLS requests from external clients, it needs to be configured with a TLS certificate and private key. For development, you can create a certificate with the `mkcert` utility that you used in chapter 3:

```
mkcert api.natter.local
```

This will spit out a certificate and private key in the current directory as two files with the `.pem` extension. PEM stands for Privacy Enhanced Mail and is a common file format for keys
