#A Load the PSK and generate an ID for it
#B Create a PSKTlsClient with the PSK
#C Override the supported versions to ensure DTLS support
#D Connect to the server and send a dummy packet to start the handshake
#E Create the DTLSClientProtocol instance and perform the handshake over UDP
#F Send encrypted packets using the returned DTLSTransport object

You can now test the handshake by running the server and client in separate terminal windows. Open two terminals and change to the root directory of the project in both. Then run the following in the first one:

```
mvn clean compile exec:java \
 -Dexec.mainClass=com.manning.apisecurityinaction.PskServer \
 -Dexec.args=changeit    #A
```

#A Specify the keystore password as an argument

This will compile and run the server class. If you've changed the keystore password, then supply the correct value on the command line. Open the second terminal window and run the client too:

```
mvn exec:java \
 -Dexec.mainClass=com.manning.apisecurityinaction.PskClient \
 -Dexec.args=changeit
```

After the compilation has finished, you'll see the client sending the lines of text to the server and the server
