receiving them.

> **NOTE** As in previous examples, this sample code makes no attempt to handle lost packets after the handshake has completed.

12.2.3 Supporting raw PSK cipher suites

By default, Bouncy Castle follows the recommendations from the IETF and only enables PSK cipher suites combined with ephemeral Diffie-Hellman key agreement to provide forward secrecy. These cipher suites are discussed in section 12.1.4. Although these are more secure than the raw PSK cipher suites, they are not suitable for very constrained devices that can't perform public key cryptography. To enable the raw PSK cipher suites you have to override the `getSupportedCipherSuites()` method in both the client and the server. Listing 12.12 shows how to override this method for the server, in this case providing support for just a single PSK cipher suite using AES-CCM to force its use. An identical change can be made to the `PSKTlsClient` object.

Listing 12.12 Enabling raw PSK cipher suites

```
var server = new PSKTlsServer(crypto,
getIdentityManager(psk)) {
    @Override
    protected ProtocolVersion[] getSupportedVersions() {
        return ProtocolVersion.DTLSv12.only();
    }
    @Override
```
