```
            throw new RuntimeException("Unable to decrypt
PSK", e);    #C
        }    #C
    }    #C
}
```

#A Create fields for the device attributes
#B Annotate the constructor so that Dalesbred knows how to load a device from the database
#C Add a method to decrypt the device PSK using NaCl's SecretBox

You can now populate the database with device profiles. Listing 13.2 shows how to initialize the database with an example device profile and encrypted PSK. Just like previous chapters you can use a temporary in-memory H2 database to hold the device details, because this makes it easy to test. In a production deployment you would use a database server or LDAP directory. You can load the database into the Dalesbred library that you've used since chapter 2, to simplify queries. Then you should create the table to hold the device profiles, in this case with simple string attributes (VARCHAR in SQL) and a binary attribute to hold the encrypted PSK. Open the Device.java file again and add the new method from the listing to create the example device database.

Listing 13.2 Populating the device database

```
static Database createDatabase(SecretBox encryptedPsk) throws
IOException {
    var pool =
JdbcConnectionPool.create("jdbc:h2:mem:devices",    #A
            "devices", "password");    #A
```
