```
var headers = CBORObject.NewMap()    #A
        .Add("If-Matches", revisionEtag);    #A
var body = CBORObject.NewMap()
        .Add("foo", "bar")
        .Add("data", 12345);
var request = CBORObject.NewMap()
        .Add("method", "PUT")    #B
        .Add("headers", headers)    #B
        .Add("body", body);    #B
var sent = CryptoBox.encrypt(clientKeys.getPrivate(),    #C
        serverKeys.getPublic(), request.EncodeToBytes());
#C
```

#A Encode any required HTTP headers into CBOR
#B Encode the headers and body, along with the HTTP method as a single object
#C Encrypt and authenticate the entire request object

To validate the request, the API server should decrypt the request object and then verify that the headers and HTTP request method match those specified in the object. If they don't match, then the request should be rejected as invalid.

> **CAUTION** You should always ensure the actual HTTP request headers match the request object rather than replacing them. Otherwise an attacker can use the request object to bypass security filtering performed by Web Application Firewalls and other security controls. You should never let a request object change the HTTP method because many security checks in web browsers rely on it.

Listing 13.15 shows how to validate a request object in a filter for the Spark HTTP framework you've used in earlier
