After VirtualBox is installed you can install a Kubernetes distribution. Minikube (https://minikub.sigs.k8s.io) is a single-node Kubernetes cluster that you can run on a developer machine. You can install minikube using Homebrew, by running

```
brew install minikube
```

Afterwards, you should configure minikube to use VirtualBox as its virtual machine by running the following command:

```
minikube config set vm-driver=virtualbox
```

You can then start minikube by running

```
minikube start \
  --kubernetes-version=1.16.2 \    #A
  --memory=4096    #B
```

#A The version of Kubernetes used in the book
#B Use 4GB of memory

> **TIP** A running minikube cluster can use a lot of power and memory. Stop minikube when you're not using it by running `minikube stop`.

Installing minikube with Homebrew will also install the `kubectl` command-line application required to configure a Kubernetes cluster. You can check that it's installed correctly by running
