from a binary to a d-ary heap can provide a consistent speedup.

2.8.2 More graphs: Prim's algorithm

Prim's algorithm computes the minimum spanning tree (MST) of an undirected, connected graph `G`.

Suppose `G` has `n` vertices. The minimum spanning tree of `G` is:

1. a tree (a connected, undirected, acyclic graph)
2. that is a subgraph of `G` with `n` vertices and
3. whose sum of edges' weights is the least possible among all of the subgraphs of `G` that are also trees and span over all `n` vertices.

Considering the graph in the example shown in the section 2.8.1, its minimum spanning tree would be the one in figure 2.14.
