separately, and adapted to the actual context we decide to operate.

For both, however, it’s possible to give a generic definition that in turn abstracts over more specific methods: listings 16.2 and 16.3 shows these definitions.

Listing 16.2 Method validateEmbedding

```
function validateEmbedding(graph, embedding)
                            #1
  n ← |graph.vertices|
  for i in {0..n-2} do
                  #2
    for j in {i+1..n-1} do

      if vertexIntersectsVertex(embedding[i], embedding[j])
then              #3
        return false
  for edge in graph.edges do
                  #4
    for vertex in graph.vertices do
                                    #5
        if vertex != edge.source and vertex != edge.destination and
            edgeIntersectsVertex(
              embeddings[indexOf(edge.source)],
              embeddings[indexOf(edge.destination)],
              embeddings[indexOf(vertex)]) then
                  #6
          return false
  return true
```

#1 Method `validateEmbedding` takes a graph and an embedding to validate, and returns true if the embedding passed the check, or false if it needs to be rejected.
#2 Cycle through all pair of vertices.
#3 Check that the two vertices don’t intersect each other. This check is context-dependent, it can be just making sure the two
