Adjacent Swaps			
Random Swaps	1692.044	1683.563	1668.248
Random Permutation	1816.658	1831.886	1913.416

Increasing the temperature decay rate from 0.97 to 0.99 means that the cooling is performed more slowly and uniformly (you can refer to figure 17.7 to visualize the decay curves). In turn, this seems to help when we use only local search around current solution, while making thing worse when for full-domain searches. The medium-range search performed through random vertices swaps gets even closer to the best cost, on average.

Listing 17.3 Random Transition Function for TSP

```
function randomStep(P)
                  #1
  which ←
randomFloat(0,1)
     #2
  if which < 0.1
then                                                    #3
    i ← randomInt(0,
|P|)                                                    #4
    swap(i, (i+1) % |P|)
  elsif which < 0.8 then
    i ← randomInt(0,
|P|)                                                    #5
    j ← randomInt(0, |P|)
    swap(i, j)
  else
```
