otherwise. Nevertheless, Θ(f(n)) would be the correct notation for the class of functions whose upper and lower bound is f(n).

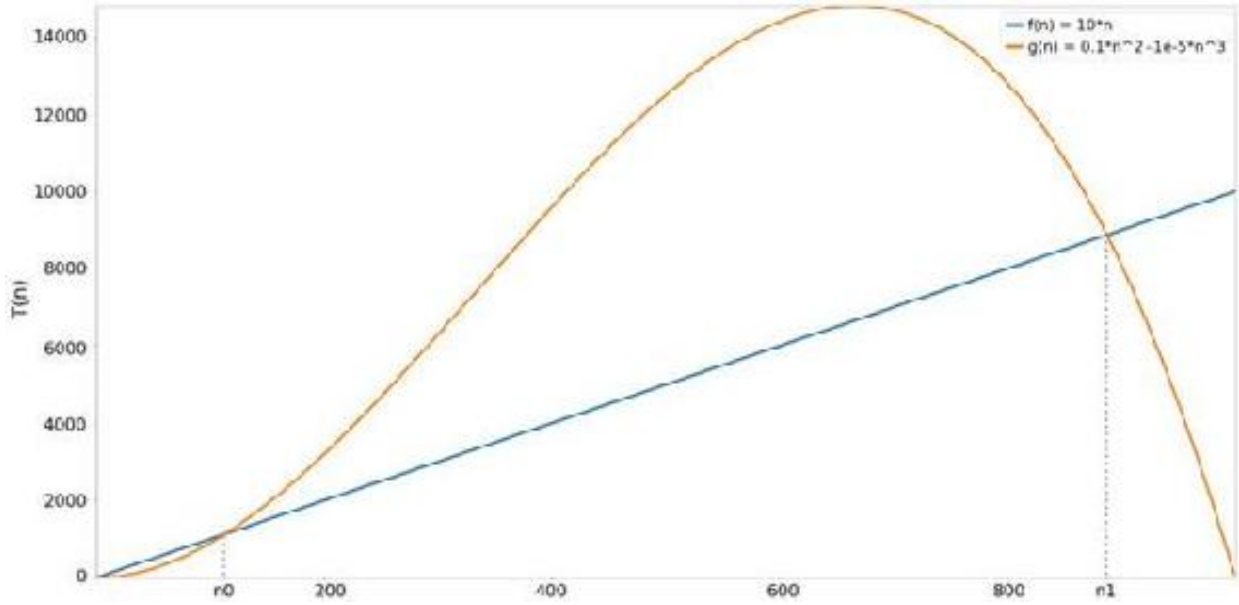

Figure B.3 An example showing why we need to be careful in drawing conclusions: while `g(n)` is larger than `f(n)` at n_0~=112, this doesn't hold true for any value of `n` $>n_0$: in fact, at n_1~=887, we have another intersection between the two functions, and after that point `f(n)` becomes again larger than `g(n)`.

Now we have all the tools we need to unequivocally describe algorithms' performance. You will see this notation in action a lot in the remaining sections of this chapter.

B.5 Examples
