more information about the quality of a model with respect to just the accuracy.

If we take Bloom filters (chapter 4) as an example, as we stated when analyzing the `contains` method (TODO: reference to section in chapter 4), when the output is `false` we can be sure it's right, so Bloom filters have a 100% recall.

Their precision, unfortunately, is not as perfect: in the section (TODO: reference) we'll delve into the details of how to compute it.

F.4.3 Other Metrics + Recap

There are, of course, other metrics that can be useful for classifiers. One of the most useful is the F-measure[4], combining precision and recall into one formula.

These alternative metrics, however, go beyond our.

[TODO: footnote reference to F-measure]

If we continue with our parallel with Bloom filters, we can recap, instead, the meaning of the metrics we examined in that context:

- *Accuracy* answer the question "what percent of calls to `contains` are correct?".
