Figure 3.6 tries to answer this question, interpreting the steps we have seen in listing 3.2 and figure 3.5 from a different point of view. Let me remark that this is just an informal way to illustrate how a rotation works, when you are going to implement this method, you'd better refer to listing 3.2 and figure 3.5.

Listing 3.3 Left Rotation

```
function lefttRotate(treap, x)
                                    #1
  if x == null or isRoot(x) then
                 #2
    throw

  y ← x.parent
                  #3
  throw-if y.right !=
x                                                    #4
  p    ← y.parent
                           #5
  if p != null then
                                    #6
    if p.left == y then
                           #7
      p.left ←
x                                                          #8
    else
      p.right ← x
  else
         #9
    treap.root ← x
  y.right ← x.left
                                   #10
  x.left ←
y
         #11
```
