

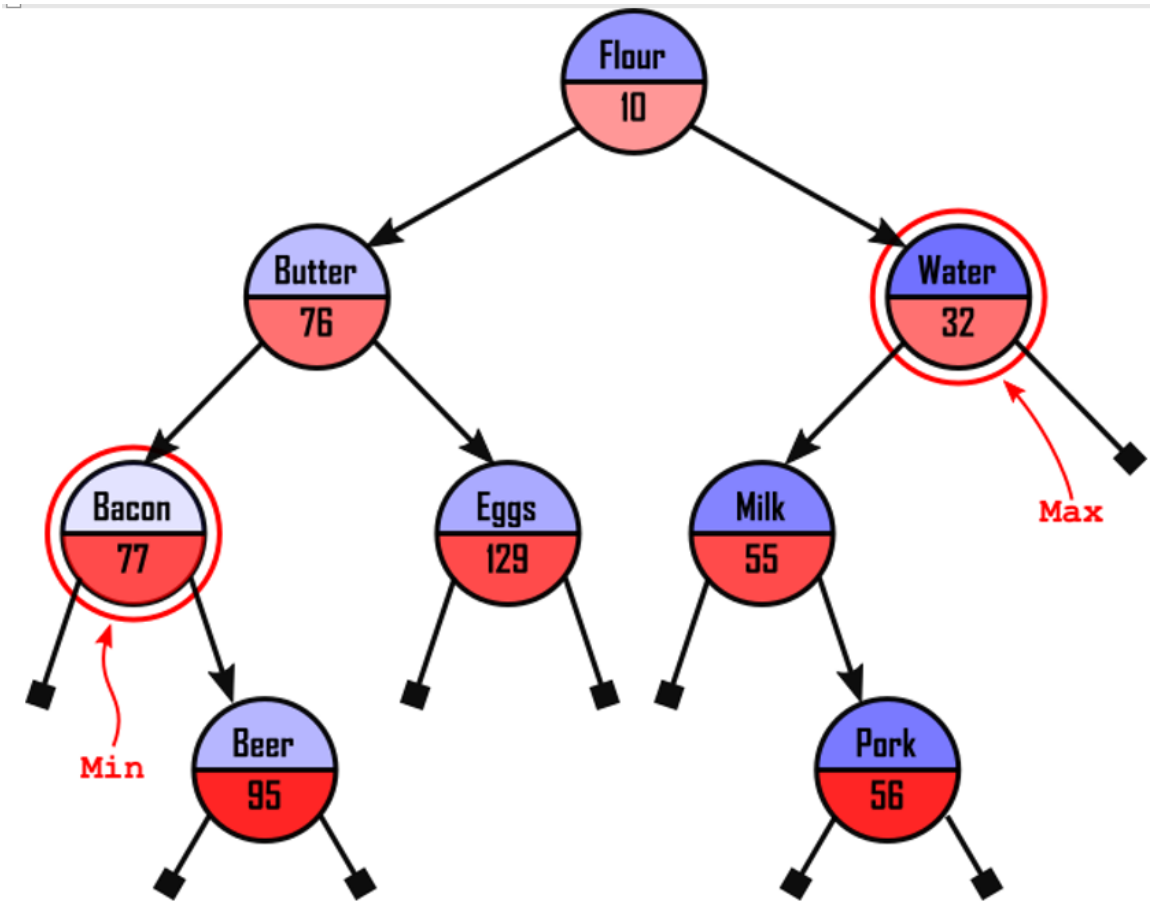

Figure 3.11 How to find minimum and maximum keys in a treap (or, in general, in a binary search tree): the minimum is stored in the left-most node, and the maximum in the right-most node. Notice how these nodes aren't necessarily tree leaves.

These keys are stored respectively in the left-most and right-most nodes of the tree; be careful though, these nodes are not necessarily going to be leaves, as shown in figure 3.11.

Listing 3.8 shows a possible implementation of method `min`: exactly like in BSTs, we just traverse the tree taking always the left branch, until we reach a node whose left child is `null`. Method `max` is symmetric, you just need to replace `node.left` with `node.right`.
