great result, if we focus on worst-cases; nevertheless, if you look at it from a different perspective, we already managed to have a more balanced set of operations on our disjoint set, which is especially nice in those contexts where `merge` is a common operation (while in read-intensive applications, where `merge` is only executed rarely, the naïve implementation could overall be preferable).

Anyway, just wait and read through next section before dismissing the tree solution: it will be worth it.

5.6 Heuristics to Improve the Running Time[12]

The next step in our quest for optimal performance is to make sure `findPartition` is logarithmic even in the worst-case scenario.
